Belinda Jones

A thesis submitted for the
Degree of Master of Science

University of Technology, Sydney

May 2006

CERTIFICATE

I certify that the work in this thesis has not been previously submitted for a degree nor has it been submitted as part of requirements for a degree except as fully acknowledged within the text.

I also certify that the thesis has been written by me. Any help that I have received in my research work and the preparation of the thesis itself has been acknowledged. In addition, I certify that all information sources and literature are included in the thesis.

Signature of Candidate

A handwritten signature in black ink, appearing to be 'BODS', is written above a horizontal line.

ACKNOWLEDGEMENTS

I would firstly like to thank for their support and help my supervisors – Mike Stevens and Professor Bob Jones. Their belief in my idea and encouragement has meant this project has finally come together.

Thanks again to Jim Keegan who makes working in the GC-MS lab a pleasure, and all the post-graduate students in my office whose many UNO games kept the sanity.

My family as always were there to support me scratching their heads as times wondering what it was I was really doing. However, as always, they have watched me follow my own path and their belief in me has never wavered which is, and will always be, appreciated more than I can possibly say. Thankyou.

To my friends, especially Lorrae, Rach, Jodes, Dan and Cara, who have put up with my frustration and absences with understanding and patience. I truly appreciate all that you have given me, and wouldn't be here without you all.

ABSTRACT

This project encompasses a detailed literature review of a variety of topics, covering fire scene examination, accelerants and present accelerant detection techniques, biosensors, the human olfactory system and electrochemical analytical techniques such as cyclic voltammetry. An overview of all these areas allows a theory to be brought together, that a biosensor could be created for the presumptive detection of accelerants at fire scenes, a sensor with a high degree of discrimination power achieved through the selectivity of specific biological agents and computerised pattern recognition fabricated into an array. As a result of the large area covered by the literature review, this project's experimental component explored the use of cyclic voltammetry as a tool to investigate the electroactive behaviour of accelerants and their extracts. Optimisation of conditions including pH, electrode type, and extraction time were also completed. The results of the research showed that no electroactive species were present in the accelerants within the detection limit of the method used. This result is important given that the future direction of this project includes the layering of an olfactory receptor onto an electrode to create a biosensor. This can be accomplished with the assurance that there will be no interference from electrode/accelerant interactions. Accelerant standards were also analysed using Gas Chromatography – Mass Spectrometry and confirmed using current fire debris sample analysis standards.
